Problem Set #1

Let X_1, X_2, \dots, X_n be n mutually independent random variables, each of which is uniformly distributed on the integers from 1 to k . Let Y denote the minimum of the X_i 's. Find the distribution of Y .

This is kind of an amazing result. The distribution of the minimum number of X_i 's can be expressed in a simple quotient.

The sample space here is the k^n since there are X_n variables uniformly distributed from 1 to k . We can then use, effectively, the *complement principle* to determine an expression for each Y value. If $Y=1$ we get $k^n - (k-1)^n$. This is the sample space minus all the X_i 's that are NOT equal to $Y=1$. We can pull a similar trick for $Y=2$, that is find all the X_i 's that are not $Y=1$ or $Y=2$ and subtract that from the sample space. Thus, $k^n - (k-2)^n - (k^n - (k-1)^n)$. If you distribute the negative sign through the last term (for $Y=1$), we see that the k^n terms cancel out (which makes sense, it's the entire space) and we are left with $(k-1)^n - (k-2)^n$.

We can do this again for $Y=3$ and get $k^n - (k-3)^n - ((k-1)^n - (k-2)^n) - (k^n - (k-1)^n)$. Again, distribute the negative and combine like terms and this reduces to $(k-2)^n - (k-3)^n$. We can safely generalize this result to $(k-j+1)^n - (k-j)^n$ for all j between 1 and k integers.

To find the distribution, we simply divide by the space of possibilities. $m(j) = \frac{(k-j+1)^n - (k-j)^n}{k^n}$ for all j between 1 and k integers. So much of math is pattern matching...

Problem Set #2

Your organization owns a copier (future lawyers, etc.) or MRI (future doctors). This machine has a manufacturer's expected lifetime of 10 years. This means that we expect one failure every ten years. (Include the probability statements and R Code for each part).

What is the probability that the machine will fail after 8 years?. Provide also the expected value and standard deviation. Model as a geometric. (Hint: the probability is equivalent to not failing during the first 8 years..)

$$E(X) = \frac{1}{p} \text{ and } \sigma = \sqrt{\frac{1-p}{p^2}}$$

```
p<-1/10
E_x<-1/p
sd<-sqrt((1-p)/p^2)
paste("Expected value:",E_x, "sd: ",sd)
```

```
## [1] "Expected value: 10 sd: 9.48683298050514"
```

R has a nice built in function to evaluate probabilities.

```
paste("probability of failure in 8 years: ",pgeom(8, p, lower.tail = F))
```

```
## [1] "probability of failure in 8 years: 0.387420489"
```

b. What is the probability that the machine will fail after 8 years?. Provide also the expected value and standard deviation. Model as an exponential.

$$\lambda e^{-(\lambda x)}$$

```
lambda<-1/10
```

```
x<-8
```

```
paste("probability of failure in 8 years: ",exp(-lambda*x))
```

```
## [1] "probability of failure in 8 years: 0.449328964117222"
```

```
E_x<-1/lambda
```

```
sd<-sqrt(1/lambda^2)
```

```
paste("Expected value:",E_x, "sd: ",sd)
```

```
## [1] "Expected value: 10 sd: 10"
```

c. What is the probability that the machine will fail after 8 years?. Provide also the expected value and standard deviation. Model as a binomial. (Hint: 0 success in 8 years)

```
n <- 8
```

```
p <- 1/10
```

```
comp <- 1-p
```

```
k <- 0
```

```
E_x<-n*p
```

```
sd<-sqrt(n*p*comp)
```

```
paste("probability of failure in 8 years: ",dbinom(k, n, p))
```

```
## [1] "probability of failure in 8 years: 0.43046721"
```

```
paste("Expected value:",E_x, "sd: ",sd)
```

```
## [1] "Expected value: 0.8 sd: 0.848528137423857"
```

d. What is the probability that the machine will fail after 8 years?. Provide also the expected value and standard deviation. Model as a Poisson.

```
lambda <- 0.8
```

```
paste("probability of failure in 8 years: ",ppois(0, lambda = lambda))
```

```
## [1] "probability of failure in 8 years: 0.449328964117222"
```

For Poisson lambda is the expected value and variance. Thus,

```
paste("Expected value:",lambda, "sd: ",sqrt(lambda))
```

```
## [1] "Expected value: 0.8 sd: 0.894427190999916"
```
